1. Identifying Key Variables in the Problem (Corresponds to Points 2 and 6)

- Analysis: The key variables involved in the question include:
  - The number of newspapers sold (unknown, to be solved for).
  - The payment structure (Zedland Daily offers a fixed income of 60 zeds plus an additional 0.05 zeds per newspaper sold).
  - Total income (74 zeds).
- Relevance: This is foundational to solving the problem, as only by clearly identifying these variables and their relationships can a mathematical model be constructed and solved.

---

2. Translating the Problem into Standard Mathematical Representation (Corresponds to Point 9)

- Analysis: The question requires converting the textual description into a mathematical equation:
  - Let the number of newspapers sold be x . Then total income is given by $60 + 0.05x = 74$.
  - Solving yields $x = (74 - 60)/0.05 = 280$.
- Relevance: This translation from problem description to mathematical solution is the core step in modeling.

---

3. Using Mathematical Tools to Describe Relationships in the Problem (Corresponds to Points 10 and 11)

- Analysis: The problem requires using algebraic tools (equations) to describe the linear relationship between income and sales volume.
- Relevance: Employing such tools is fundamental to mathematical modeling, as it clearly expresses the relationship between variables.

---

4. Recognizing the Mathematical Structure of the Problem (Corresponds to Point 5)

- Analysis: The problem implicitly involves a linear function:
  - Income = Fixed income + Variable income (proportional to the number of newspapers sold).
  - This structure is common in real-life contexts (e.g., base salary + commission).
- Relevance: Understanding this mathematical structure helps students connect real-world situations with appropriate mathematical models.

5. Simplifying or Decomposing the Problem for Mathematical Analysis (Corresponds to Point 7)

- Analysis: The problem requires decomposing total income into fixed and variable components:
  - Fixed component: 60 zeds.
  - Variable component: 0.05 zeds × number of newspapers sold.
- Relevance: This decomposition simplifies the problem and makes it more approachable through algebraic methods.

---

6. Identifying Constraints and Assumptions in the Problem (Corresponds to Point 12)

- Analysis: The problem implicitly includes certain assumptions:
  - The payment scheme remains unchanged (fixed income plus per-copy bonus).
  - The number of newspapers sold is an integer (a reasonable assumption in real-world contexts).
- Relevance: These assumptions ensure the problem is solvable and aligned with realistic scenarios.

---

7. Choosing an Appropriate Mathematical Representation for the Context (Corresponds to Point 3)

- Analysis: The problem calls for using an algebraic equation as the representation tool, rather than alternatives like graphs or tables.
- Relevance: An algebraic equation is the most direct and efficient method to accurately describe the linear relationship and solve for the unknown.

1. 识别问题中的关键变量（对应第2点和第6点）

- 分析：题目中涉及的关键变量包括：
  - 报纸销售数量（未知，需要求解）。
  - 报酬结构（Zedland Daily 的固定收入 60 zeds + 每份报纸 0.05 zeds 的额外收入）。
  - 总收入（74 zeds）。
- 相关性：这是解决问题的基础，因为只有明确这些变量及其关系，才能建立数学模型并求解。

---

2. 将问题转化为标准数学表示（对应第9点）

- 分析：题目要求将文字描述转化为数学方程：
  - 设销售数量为 x ，则总收入为 $60 + 0.05x = 74$ 。
  - 解方程得 $x = (74 - 60)/0.05 = 280$ 。
- 相关性：这是从问题描述到数学解答的核心转化过程。

---

3. 使用数学工具描述问题中的关系（对应第10点和第11点）

- 分析：题目需要使用代数工具（方程）来描述收入与销售数量之间的线性关系。
- 相关性：这种工具的使用是数学建模的基本要求，能够清晰表达变量间的关系。

---

4. 识别问题中的数学结构（对应第5点）

- 分析：题目隐含了一个线性函数的数学结构：
  - 收入 = 固定收入 + 变动收入（与销售数量成正比）。
  - 这种结构在现实生活中很常见（如基本工资 + 提成）。
- 相关性：理解这种数学结构有助于学生将实际问题与数学模型联系起来。

---

5. 简化或分解问题以便进行数学分析（对应第7点）

- 分析：题目需要将总收入分解为固定部分和变动部分：
  - 固定部分：60 zeds。
  - 变动部分：0.05 zeds × 销售数量。
- 相关性：这种分解简化了问题，使其更容易通过代数方法解决。

6. 识别问题中的约束和假设（对应第12点）

- 分析：题目隐含了一些假设：
  - 报酬规则不变（固定收入加每份报纸的额外收入）。
  - 销售数量为整数（实际情境中的合理假设）。
- 相关性：这些假设确保了问题的可解性，并符合现实情境。

---

7. 选择适合问题情境的数学表示（对应第3点）

- 分析：题目需要选择代数方程作为表示工具，而不是其他形式（如图形或表格）。
- 相关性：代数方程是最直接且高效的方式，能够准确描述线性关系并求解未知数。
